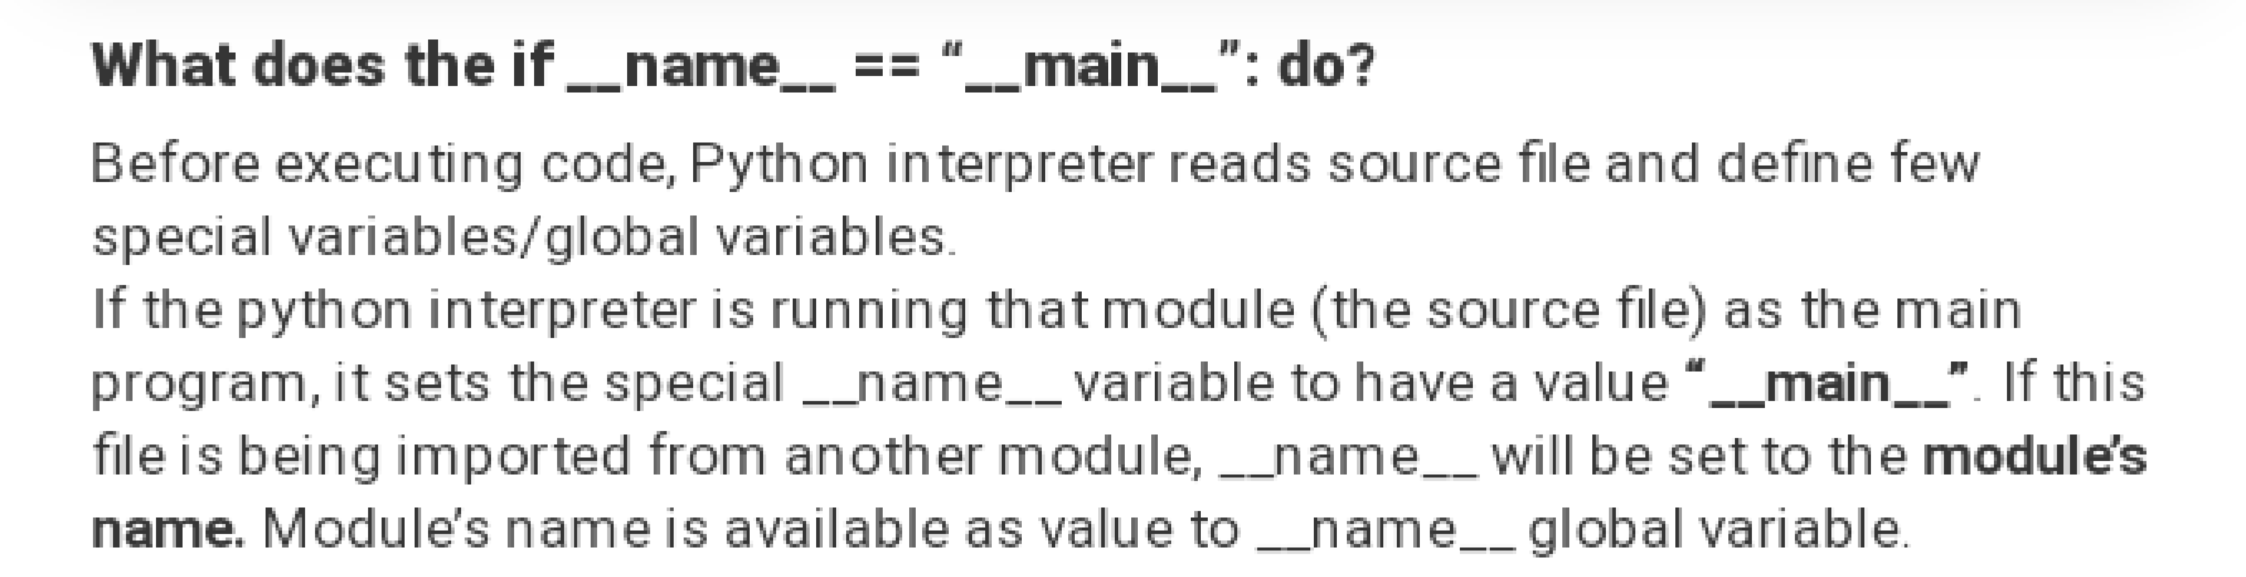
Python

PYTHON
if __name__ ==
"__main__"



What does the if __name__ == “__main__”: do?

Before executing code, Python interpreter reads source file and define few special variables/global variables.
If the python interpreter is running that module (the source file) as the main program, it sets the special __name__ variable to have a value **“__main__”**. If this file is being imported from another module, __name__ will be set to the **module’s name.** Module’s name is available as value to __name__ global variable.

A module is a file containing Python definitions and statements. The file name is the module name with the suffix .py appended.

When we execute file as command to the python interpreter,

```
python script.py
```

Python3

```
# Python program to execute
# main directly
print ('Always executed')

if __name__ == '__main__':
    print ('Executed when invoked directly')
else:
    print ('Executed when imported')
```

- All of the code that is at indentation level 0 [Block 1] gets executed. Functions and classes that are defined are, well, defined, but none of their code runs.
- Here, as we executed script.py directly __name__ variable will be **__main__**. So, code in this if block[Block 2] will only run if that module is the entry point to your program.
- Thus, you can test whether your script is being run directly or being imported by something else by testing __name__ variable.
- If script is getting imported by some other module at that time **__name__** will be module name.

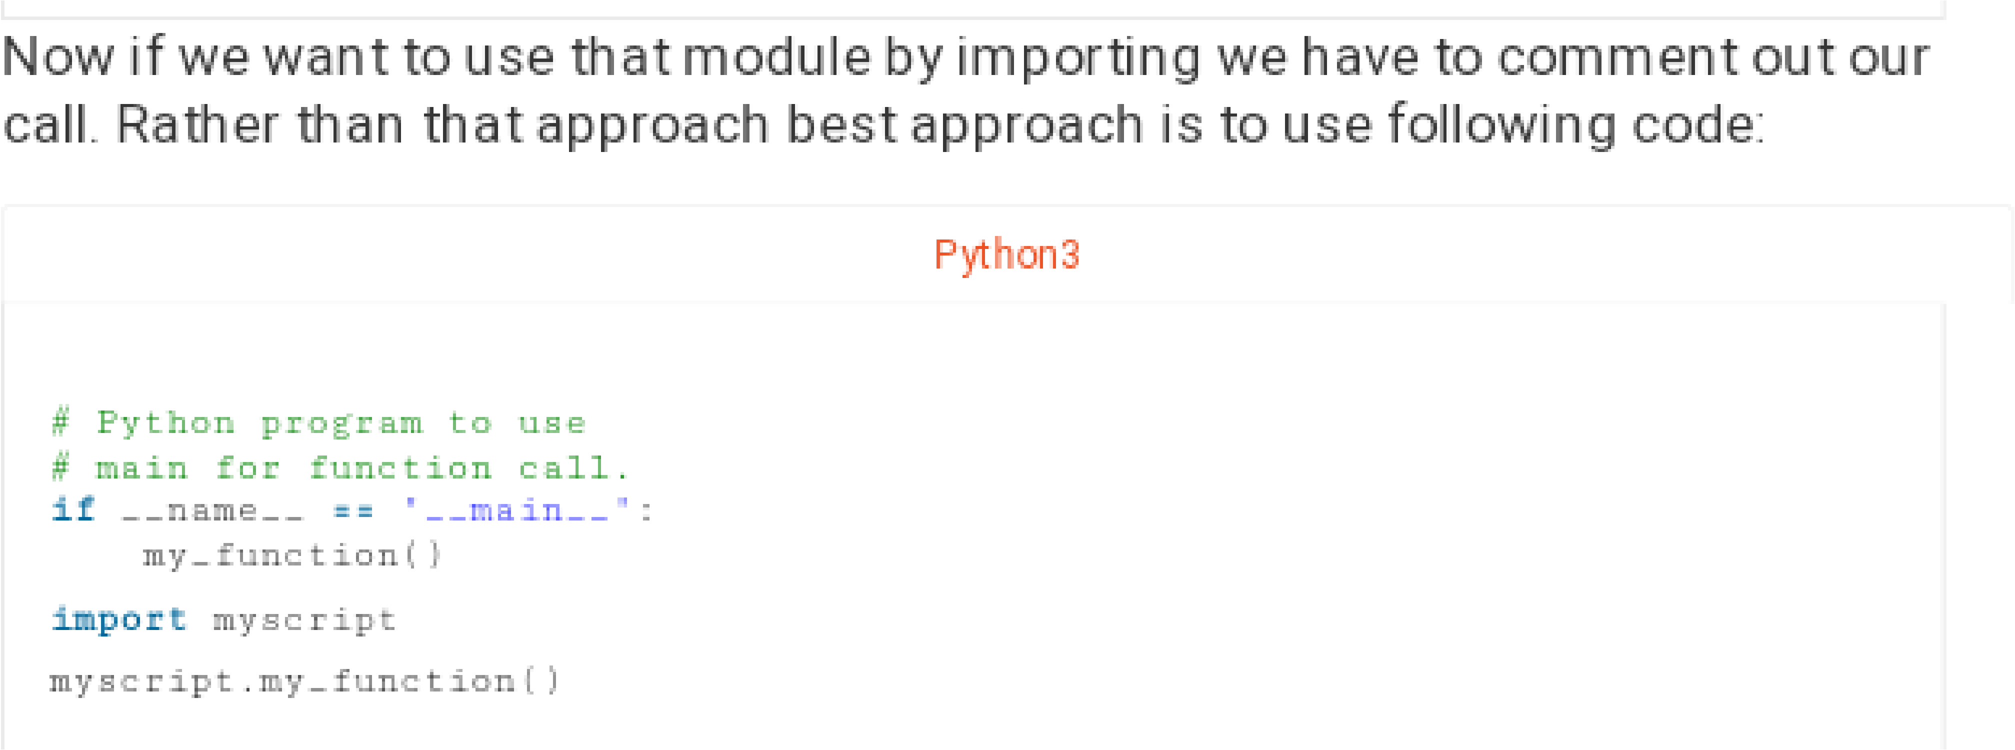
Why Do we need it?

For example we are developing script which is designed to be used as module:

Python3

```
# Python program to execute
# function directly
def my_function():
    print ('I am inside function")

# We can test function by calling it.
my_function()
```

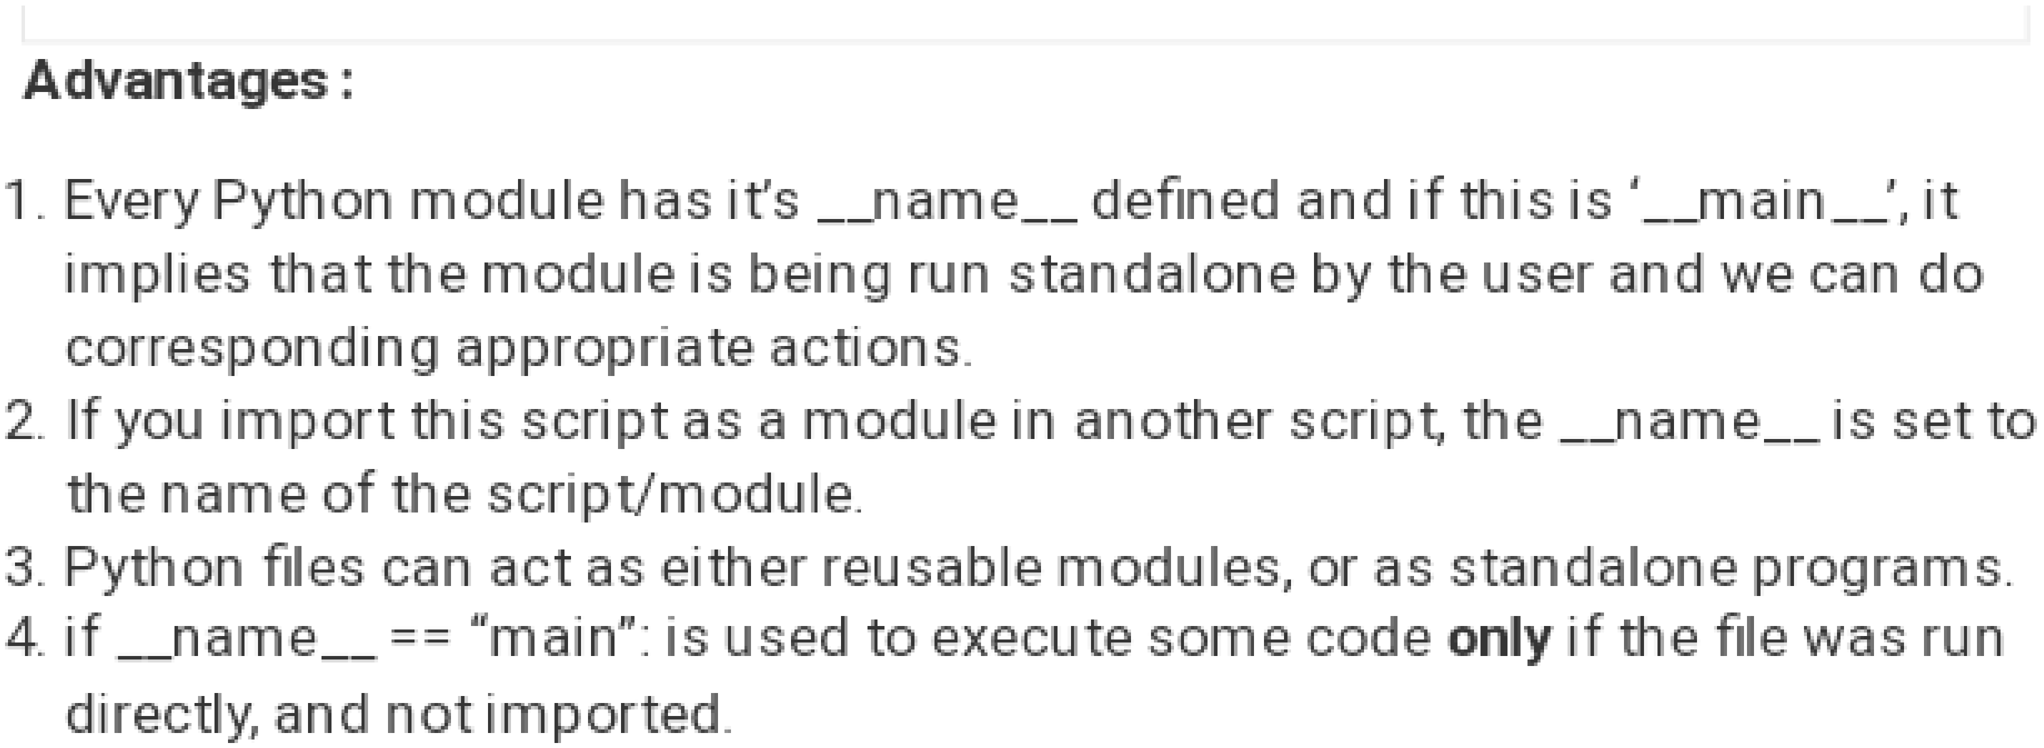


Now if we want to use that module by importing we have to comment out our call. Rather than that approach best approach is to use following code:

```
# Python program to use
# main for function call.
if __name__ == '__main__':
    my_function()

import myscript

myscript.my_function()
```



Advantages :

1. Every Python module has it's __name__ defined and if this is '__main__', it implies that the module is being run standalone by the user and we can do corresponding appropriate actions.
2. If you import this script as a module in another script, the __name__ is set to the name of the script/module.
3. Python files can act as either reusable modules, or as standalone programs.
4. if __name__ == "main": is used to execute some code **only** if the file was run directly, and not imported.
